

Ans of the Question 1

Software Development Life Cycle (SDLC)

Explanation of SDLC workflow:

1. Requirement phase:

The team discuss and get Business requirements, Customer needs, Budget and resources, Technical requirements from client. The planning of product got finalized in this stage.

2. Design Phase:

The team decides how the system will work and how will be the System architecture, UI/UX design, Technology selection and so on.

3. Development Phase:

Developers write the actual source code based on the requirements and design

4. Testing Phase:

QA engineers verify the quality of software and checks whether the software works correctly or not by many testing like functional testing, regression testing, API testing etc.

5. Deployment Phase:

After finishing all testing and fixing software is released to users

6. Maintenance:

After releasing the software the team fix new bugs, Improves performance, Adds new features, Applies security patches and maintain the software

Ans of the Question 2

Explanation of

1. What the AI did well

- AI generated multiple user stories within seconds and also followed the standard. It broke the five user stories into granular tasks with role assignments, time estimates, and priority levels.
- It created acceptance criteria organized and logical.
- It created a structured Sprint Backlog.
- The output remained logically consistent across all three prompts
- The main thing is it saved the time very much.

2. What corrections did you make

- I made corrections in Acceptance Criteria with edge cases like session timeout during checkout or simultaneous stock depletion.
- I made corrections in Sprint Backlog by increasing the estimated time and added a dependency column.
- I added DoD in the backlog.
- Added a column to flag high-risk tasks so that QA can prioritize deeper testing there.

3. Why human review is still necessary

-
- The AI doesn't know the actual size of team, business rules or client constraints. That's why a real human have to review this.
 - Prioritization decisions require business and stakeholder input that AI cannot access.
 - AI-generated acceptance criteria and tasks can miss edge cases or company-specific compliance requirements that only a human QA analyst would catch.
 - In a real SQA process, requirements and test artifacts must be traceable and approved by a responsible person
 - Blindly accepting AI output risks embedding subtle logical or contextual errors into the sprint plan.
 - AI's some output maybe estimated and assumption that's why it must be validated against real project data

T16	Product Reviews	Implement review submission (verified purchase check)	Dev - Backend	7	Low	To Do
T17	Product Reviews	Test review functionality (edge cases, flagging)	QA	5	Low	To Do

Total Estimated Effort: 102 hours

Sprint Backlog Notes:

- **Priority** is based on core purchase flow (Search → Cart → Checkout) taking precedence over secondary features (Tracking, Reviews).
- **Status** column should be updated daily during standups (To Do → In Progress → In Review → Done).
- A **Burndown Chart** should track remaining estimated hours against sprint days to monitor progress.

Want me to also generate a **Burndown Chart** (as a visual) or a **Test Plan** document mapping these tasks to specific QA test cases?
